Effects of integrating hip movements into bridge exercises on electromyographic activities of selected trunk muscles in healthy individuals

Manual Therapy 2013; November 10: Epub ahead of print

This study aimed to identify the electromyographic (EMG) effects in selected trunk muscles after incorporating hip movement into bridging exercise.

Twenty-six healthy adults (13 men and 13 women) volunteered for this experiment. EMG data (% maximum voluntary isometric contraction) were recorded from the rectus abdominis (RA), obliquus internus (OI), erector spinae (ES), and multifidus (MF) muscles of the dominant side while the subjects performed 3 types of bridging exercise, including bridging alone (Bridging 1), bridging with unilateral hip movements (Bridging 2), and bridging with bilateral hip movements (Bridging 3) in a sling suspension system.

The RA and OI showed greater EMG activity during Bridging 2 and 3 compared to Bridging 1, with the greatest OI activity during Bridging 3 than during Bridging 1 and 2 (p < 0.05). Furthermore, the OI/RA and MF/ES ratios were significantly higher for Bridging 2 (OI/RA ¼ 1.89 1.41; MF/ES ¼ 1.03 0.19) and Bridging 3 (OI/RA ¼ 2.34 1.86; MF/ES ¼ 1.03 0.15) than Bridging 1 (IO/RA ¼ 1.35 0.92; MF/ES ¼ 0.98 0.16). The OI/RA ratio was significantly higher for Bridging 3 than for Bridging 2.

Based on these results, adding hip abduction and adduction, particularly bilateral movements, could be a useful method to enhance OI and MF EMG activity and their activities relative to global muscles during bridging exercise.

Effects of Bridging Exercise on Different Support Surfaces on the Transverse Abdominis.

**Purpose:** The purpose of this study was to identify the effects of bridging exercise on different support surfaces on the thickness of the musculus transversus abdominis and lower extremity muscle activities.

**Subjects:** Thirty-five students of H University. [Methods] The experimental group (n=18) performed bridging exercise on the sling support surface, and the control group (n=17) performed bridging exercise on a general support surface.

**Results:** Thickness changes in the musculus transversus abdominis were 0.35 cm in the experimental group, and 0.17 cm in the control group, suggesting that the experimental group showed a more significant change. For the lower extremity muscular activity, there was a significant difference between the experimental group and the control group only in the biceps femoris muscle.

**Conclusion:** Based on these results, we consider that bridging exercise on a sling support surface would increase the thickness of the transversus abdominis and lower extremity muscle activities in rehabilitation programs for patients with back pain.

**Key words:** Bridging exercise, Sling exercise, Transversus abdominis

The Effects of Sling Exercise Using Vibration on Trunk Muscle Activities of Healthy Adults.
*Journal of Physical Therapy Science* 2013;25:1291–4

**Purpose:** This study compared the effects of sling exercises with and without vibration on the muscular activity of the internal oblique (IO), rectus abdominis (RA), multifidus (MF), and erector spinae (ES) muscles of healthy adults.

**Methods:** Eleven healthy university students (11 men) with a mean age of 22.8 years were enrolled in this study. Subjects performed supine and prone bridge exercises with the knees flexed using a sling suspension system with and without vibration. The amplitudes of the EMG activities of selected trunk muscles (internal oblique, rectus abdominis, erector spinae, multifidus) were recorded. Two types of exercise conditions were executed in a random sequence for 5 seconds each. The signals detected from the middle 3 seconds (after discarding the signals of the first and the last one seconds) were used in the analysis. A 3-minute break was given after each exercise to minimize muscle fatigue.

**Results:** During the supine bridge exercise with vibration, the activities of the IO, RA, MF, and ES muscles were significantly higher than those of the supine bridge exercise without vibration. Additionally, during the prone bridge exercise with vibration, the activities of the IO, RA, MF, and ES were significantly higher than those of the prone bridge exercise without vibration.

**Conclusion:** Sling exercises with vibration improved the trunk muscle activities of healthy adults compared to the sling exercises without vibration. The information presented here is important for clinicians who use lumbar stabilization exercises as an evaluation tool or a rehabilitation exercise.

**Key words:** Sling exercise, Vibration, Trunk muscle
Purpose: This study aimed to examine the effects of the Neurac sling exercise on postural balance adjustment and muscular response patterns in chronic low back pain (CLBP) patients.

Subjects and Methods: Sixteen CLBP patients participated in this study. They were randomly and equally assigned to group I, whose members received ordinary physical therapy (40 minutes per time, four times per week), and group II, whose members performed a lumbar stabilization exercise using the Neurac sling after ordinary physical therapy (40 minutes per time, four times per week). The visual analogue scale (VAS) and Oswestry Disability Index (ODI) were used to evaluate exercise effects. BioRescue and electromyography were utilized for the measurement of changes in postural balance adjustment and muscular response patterns, respectively.

Results: Both groups saw their VAS and ODI decrease significantly. There were significant decreases in both groups in posturography as well, but group II recorded a greater decrease. There were significant increases in the flexion–relaxation ratio in both groups, and there were significant increases in the extension–flexion ratio in the left L1–2 of group I and in all elements of group II.

Conclusion: Lumbar stabilization exercise using the Neurac sling is effective in decreasing pain, improving damaged postural balance adjustment, and normalizing muscle response patterns of CLBP patients.

Key words: Chronic low back pain (CLBP), Neurac sling exercise, Postural balance adjustment

Shoulder muscle activation levels during four closed kinetic chain exercises with and without Redcord slings.

Journal of Strength and Conditioning Research 2013;October 29:Epub ahead of print

During resistance training protocols, people are often encouraged to target the scapular stabilizing musculature (middle and lower trapezius and serratus anterior) while minimizing shoulder prime mover activation (upper trapezius and large glenohumeral muscles) in their training regime, especially in overhead athletes with scapular dyskinesis. In order to increase the activation levels in the stabilizing muscles without drastically increasing the activation in the prime movers, unstable surfaces are frequently used during closed kinetic chain exercises (CKC). However, the specific influence of Redcord slings (RS) as an unstable surface tool on the shoulder muscle activation levels have rarely been investigated, despite these results may be used for adequate exercise selection. Therefore, a controlled laboratory study was performed on 47 healthy subjects (22 ± 4.31 yr; 176 ± 0.083 cm; 69± 8.57 kg) during four CKC exercises without and with RS: half push-up, knee push-up, knee prone bridging plus, and pull-up. When using RS, serratus anterior muscle activation decreased during the knee push-up and knee prone bridging plus exercise. In addition, a drastic increase in pectoralis major muscle activation was found during the half push-up and knee prone bridging plus exercise. Consequently, the use of RS does not necessarily imply that higher levels of scapular stabilizer muscle activation will be attained. These findings suggest RS might be an appropriate training tool when used within a general strengthening program, but should not be preferred over a stable base of support when training for specific scapular stabilization purposes.

Core Strength Training Using a Combination of Home Exercises and a Dynamic Sling System for the Management of Low Back Pain in Pre-professional Ballet Dancers.

Estimates of low back pain prevalence in USA ballet dancers range from 8% to 23%. Lumbar stabilization and extensor muscle training has been shown to act as a hypoalgesic for low back pain. Timing and coordination of multifidi and transverse abdominis muscles are recognized as important factors for spinal stabilization. The purpose of this study was to explore the effects of training methods using home exercises and a dynamic sling system on core strength, disability, and low back pain in pre-professional ballet dancers. Five participants were randomly assigned to start a traditional unsupervised lumbar stabilization home exercise program (HEP) or supervised dynamic sling training to strengthen the core and lower extremities. Measurements were taken at baseline and at weeks 3 and 6 for disability using the Patient Specific Functional Scale (PSFS), pain using the Numerical Pain Rating System (NPRS), core strength and endurance using timed plank, side-plank, and bridge positions, and sciatic nerve irritability using the straight leg raise (SLR). Data were analyzed using descriptive statistics. From initial to final measurements, all participants demonstrated an improvement in strength and SLR range, and those with initial pain and disability reported relief of symptoms. These results suggest that dynamic sling training and a HEP may help to increase strength, decrease pain, and improve function in dancers without aggravating sciatic nerve irritation.
Lee SY, Lee DH, Park JS.

Purpose: The purpose of the present study was to examine the effects of changes in hand position on the electromyographic activities of the shoulder stabilizer muscles during push-up plus exercises (PUPE) on unstable surfaces.

Subjects: The subjects of the present study were normal adults in their 20s (n=15). PUPEs were performed with the hands in the neutral positions (NP), internal rotation positions (IRP), and external rotation positions (ERP) using a sling device for the unstable surface.

Methods: We measured the electromyographic activities of the wrist flexor (WF), the wrist extensor (WE), the biceps brachii (BB), the triceps brachii (TB), the upper trapezius (UT), the lower trapezius (LT), the serratus anterior (SA), and the pectoralis major (PM). The muscle activities were compared and analyzed using electromyography.

Results: When hand position changed, WF activity in NP, and SA activity in ERP were significantly different from their respective activities in the other positions.

Conclusion: To selectively enhance the electromyographic activity of the SA during PUPE using a sling device as an unstable surface, we consider performance of PUPE in ERP is an effective intervention.

Radiographic Imaging Analysis after Sling Exercises for Hemiplegic Shoulder Subluxation. 

**Purpose:** The aim of this study was evaluate the effect of a sling exercise on shoulder subluxation in stroke patients.

**Subjects:** The subjects of this study were thirty-four stroke patients with subluxation. They were randomly selected and divided into two groups.

**Methods:** The subject group (n=17) performed the sling exercise with traditional therapeutic exercise. The control group (n=17) performed only traditional therapeutic exercise.

**Results:** The results indicate that improvement of corrected vertical distance (cVD), and the ratio of the oblique distance of the affected and unaffected sides (rOD) was greater in the experimental group than in the control group.

**Conclusion:** We suggest that the sling exercise is effective at reducing the severity of hemiplegic shoulder subluxation in post-stroke patients.

**Key words:** Radiographic imaging, Sling exercise, Shoulder subluxation

The Effect of Core Stabilization Exercises Using a Sling on Pain and Muscle Strength of Patients with Chronic Low Back Pain.

*Journal of Physical Therapy Science* 2012;24(8):671-4

Abstract. [Purpose] This study examined the feasibility of using an intervention of core stabilization exercises using a sling to control pain and muscle strength of patients with chronic low back pain. [Subjects] The subjects, 30 chronic low back patients, were divided randomly into two exercise groups: one group performed core stabilization exercises using a sling (n=15), and the other group performed mat exercises group (n=15). Each exercise program was performed three days per week for four weeks. Pain and muscle strength were measured before and after the intervention. Pain was assessed using a visual analogue scale (VAS) and muscle strength was measured with a Jurgune device. [Results] The differences in the VAS scores for the sling exercise and mat exercise program were statistically significant between pre and post intervention in both groups. Muscle strength increases were also statistically significant. However, the comparison of sling exercise and mat exercise program showed no statistically significant differences between the groups, post-intervention. [Conclusion] Both the sling exercise and the mat exercise program reduced chronic low back pain improved patients’ lumbar muscle strength, and decreased VAS scores; and the sling exercise was more effective than the mat exercise program. Further study is needed to develop the sling exercise for effective use in clinical practice for the treatment of chronic low back pain.

Study Design. A randomized controlled trial. Objective. To investigate feed-forward activation or timing of abdominal muscle activation in response to rapid shoulder flexion after 8 weeks with core stability exercises, sling exercises, or general exercises in chronic non specific low back pain (LBP) patients. Summary of Background Data. Delayed onset in abdominal muscles has been associated with LBP. Low load exercises to volitionally activate the transversus abdominis were introduced to restore trunk muscle activation deficits. More forceful co-contraction exercises have been advocated by others. This study explored whether abdominal muscle onset changed after low-load core stability exercises, high-load sling exercises, or general exercises. Methods. Subjects (N = 109) with chronic non specific LBP of at least 3 months' duration were randomly assigned to 8 weekly treatments with low-load core stability exercises, high-load stabilizing exercises in slings, or general exercises in groups. Primary outcome was onset recorded bilaterally by m-mode ultrasound imaging in the deep abdominal muscles in response to rapid shoulder flexion. Results. No or small changes were found in onset after treatment. Baseline adjusted between group differences showed a 15 ms (95% confidence interval [CI], 1–28; P = 0.03) and a 19 ms (95% CI,5–33; P < 0.01) improvement with sling relative to core stability and general exercises, respectively, but on 1 side only. There was no association between changes in pain and onset over the intervention period ( R 2 ≤ 0.02). Conclusion. Abdominal muscle onset was largely unaffected by 8 weeks of exercises in chronic LBP patients. There was no association between change in onset and LBP. Large individual variations in activation pattern of the deep abdominal muscles may justify exploration of differential effects in subgroups of LBP.

Comparison of trunk muscle activity during bridging exercises using a sling in patients with low back pain.

The aims of this study were to compare the activation of global and local muscles of the trunk during bridging with sling exercise (BSE), bridging with ball exercise (BBE), and normal bridging exercise (NBE) and to conduct and analyze these exercises in supine and prone positions to prove the effectiveness of sling exercises. Thirty patients with current low back pain (LBP) were recruited. In the supine and prone bridging exercise, each subject lifted their pelvis with their legs and feet in contact with the sling, ball, or normal surface. The electrical activities of the inferior oblique (IO), rectus abdominis (RA), multifidus (MF), and erector spinae (ES) muscles during the bridging exercises on the 3 surfaces were measured using surface electromyography (sEMG). For normalization, maximum sEMG signals were evaluated during each maximum voluntary isometric contraction (MVIC) maneuver. The root mean square during the exercise was normalized as a percentage of the MVIC (%MVIC). In the supine and prone positions, %MVIC of the IO, RA, MF, and ES during BSE was significantly higher than those during BBE and NBE (p < 0.05). In the supine position, %MVIC of the RA and ES during BBE was significantly higher than that during NBE (p < 0.05). In the prone position, all %MVIC during BBE were significantly higher than NBE (p < 0.05). These results verify the theory that the use of an unstable surface increases the activation of global and local trunk muscles during bridging exercises in the supine and prone positions. In conclusion, the use of BSE in a rehabilitation program may have therapeutic effects for patients with LBP by increasing trunk muscle activation.

The effect of traditional bridging or suspension-exercise bridging on lateral abdominal thickness in individuals with low back pain.

*Journal of Sport Rehabilitation* 2012;21:151-60

**Context:** Individuals with low back pain (LBP) are thought to benefit from interventions that improve motor control of the lumbopelvic region. It is unknown if therapeutic exercise can acutely facilitate activation of lateral abdominal musculature. **Objective:** To investigate the ability of 2 types of bridging-exercise progressions to facilitate lateral abdominal muscles during an abdominal drawing-in maneuver (ADIM) in individuals with LBP. **Design:** Randomized control trial. **Setting:** University research laboratory. **Participants:** 51 adults (mean ± SD age 23.1 ± 6.0 y, height 173.6 ± 10.5 cm, mass 74.7 ± 14.5 kg, and 64.7% female) with LBP. All participants met 3 of 4 criteria for stabilization-classification LBP or at least 6 best-fit criteria for stabilization classification. **Interventions:** Participants were randomly assigned to either traditional-bridge progression or suspension-exercise-bridge progression, each with 4 levels of progressive difficulty. They performed 5 repetitions at each level and were progressed based on specific criteria. **Main Outcome Measures:** Muscle thickness of the external oblique (EO), internal oblique (IO), and transversus abdominis (TrA) was measured during an ADIM using ultrasound imaging preintervention and postintervention. A contraction ratio (contracted thickness:resting thickness) of the EO, IO, and TrA was used to quantify changes in muscle thickness. **Results:** There was not a significant increase in EO (F1,47 = 0.44, P = .51) or IO (F1,47 = .30, P = .59) contraction ratios after the exercise progression. There was a significant (F1,47 = 4.05, P = .05) group-by-time interaction wherein the traditional-bridge progression (pre = 1.55 ± 0.22; post = 1.65 ± 0.21) resulted in greater (P = .03) TrA contraction ratio after exercise than the suspension-exercise-bridge progression (pre = 1.61 ± 0.31; post = 1.58 ± 0.28). **Conclusion:** A single exercise progression did not acutely improve muscle thickness of the EO and IO. The magnitude of change in TrA muscle thickness after the traditional-bridging progression was less than the minimal detectable change, thus not clinically significant.

Knee-extension exercise’s lack of immediate effect on maximal voluntary quadriceps torque and activation in individuals with anterior knee pain.

*Journal of Sport Rehabilitation* 2012;21:119-26

Context: Weight-bearing (WB) and non-weight-bearing (NWB) exercises are commonly used in rehabilitation programs for patients with anterior knee pain (AKP). Objective: To determine the immediate effects of isolated WB or NWB knee-extension exercises on quadriceps torque output and activation in individuals with AKP. Design: A single-blind randomized controlled trial. Setting: Laboratory. Participants: 30 subjects with self-reported AKP. Interventions: Subjects performed a maximal voluntary isometric contraction (MVIC) of the quadriceps (knee at 90°). Maximal voluntary quadriceps activation was quantified using the central activation ratio (CAR): CAR = MVIC/(MVIC + superimposed burst torque). After baseline testing, subjects were randomized to 1 of 3 intervention groups: WB knee extension, NWB knee extension, or control. WB knee-extension exercise was performed as a sling-based exercise, and NWB knee-extension exercise was performed on the Biodex dynamometer. Exercises were performed in 3 sets of 5 repetitions at approximately 55% MVIC. Measurements were obtained at 4 times: baseline and immediately and 15 and 30 min postexercise. Main Outcome Measures: Quadriceps torque output (MVIC: N·m/Kg) and quadriceps activation (CAR). Results: No significant differences in the maximal voluntary quadriceps torque output (F2,27 = 0.592, P = .56) or activation (F2,27 = 0.069, P = .93) were observed among the 3 treatment groups. Conclusions: WB and NWB knee-extension exercises did not acutely change quadriceps torque output or activation. It may be necessary to perform exercises over a number of sessions and incorporate other disinhibitory interventions (eg, cryotherapy) to observe acute changes in quadriceps torque and activation.

Keywords: central activation ratio, strengthening exercise, sling-based exercise unit

Sling Exercise and Traditional Warm-Up Have Similar Effects on the Velocity and Accuracy of Throwing.

*Journal of Strength and Conditioning Research* 2011;25(2):464-71

Throwing is a complex motion that involves the entire body and often puts an inordinate amount of stress on the shoulder and the arm. Warm-up prepares the body for work and can enhance performance. Sling-based exercise (SE) has been theorized to activate muscles, particularly the stabilizers, in a manner beneficial for preactivity warm-up, yet this hypothesis has not been tested. Our purpose was to determine if a warm-up using SE would increase throwing velocity and accuracy compared to a traditional, thrower’s 10 warm-up program. Division I baseball players (nonpitchers) (16 men, age: 19.6 ± 1.3, height: 184.2 ± 6.2 cm, mass: 76.9 ± 19.2 kg) volunteered to participate in this crossover study. All subjects underwent both a warm-up routine using a traditional method (Thrower’s 10 exercises) and a warm-up routine using closed kinetic chain SE methods (RedCord) on different days separated by 72 hours. Ball velocity and accuracy measures were obtained on 10 throws after either the traditional and SE warm-up regimens. Velocity was recorded using a standard Juggs radar gun (JUGS; Tualatin, OR, USA). Accuracy was recorded using a custom accuracy target. An Analysis of covariance was performed, with the number of throws recorded before the testing was used as a covariate and p < 0.05 was set a priori. There were no statistical differences between the SE warm-up and Thrower’s 10 warm-up for throwing velocity (SE: 74.7 ± 7.5 mph, Thrower’s 10: 74.6 ± 7.3 mph p = 0.874) or accuracy (SE: 115.6 ± 53.7 cm, Thrower’s 10: 91.8 ± 55 cm, p = 0.136). Warming up with SE produced equivalent throwing velocity and accuracy compared to the Thrower’s 10 warm-up method. Thus, SE provides an alternative to traditional warm-up.

KEY WORDS collegiate baseball players, Redcord, core, Thrower’s 10
Strength training often combines closed-kinetic-chain exercises (CKCEs) and open kinetic-chain exercises (OKCEs). The CKCE may be more effective for improving performance in lower-body training. Recently, we reported upper-body CKCE (using a commercially available system of ropes and slings, Redcord AS, Staubo, Norway) was as effective as OKCE training for strength gains and that CKCE was more effective than OKCE for improving throwing performance. To our knowledge the effectiveness of a strength training program that uses exclusively CKCE is unknown. In this study, we examined the effectiveness of CKCE vs. OKCE strength training programs in women enrolled in an introductory strength training program. Twenty-six participants were randomized to OKCE (traditional exercises) or CKCE (sling-based exercises). Participants completed 6 sets per week for 13 weeks. Pre and posttraining evaluations included the following: 1 repetition maximum (1RM) leg and bench press; sling exercise push-ups; isokinetic dynamometry; lateral step-down test; and the Star Excursion Balance Test. Both groups significantly improved bench press (by an average of 4–6 kg) and leg press (by an average of 23–35 kg) (p < 0.001). There was a significant group x time interaction (p < 0.001) for sling exercise push-ups (OKCE pre = 5.5 ± 6.8, OKCE post = 6.1 ± 8.2, CKCE pre = 6.8 ± 6.0, CKCE post = 16.9 ± 6.6). Isokinetic measures of knee extension, knee flexion, shoulder internal rotation, and shoulder external rotation increased (improvements ranged from 2.7 to 27.7%), with no group differences. Both OKCE and CKCE strength training elicited similar changes in balance. We conclude that CKCE training is equally as effective as OKCE training during the initial phases of a strength training program in women. The fact that only CKCE improved sling exercise push-ups supports previous findings suggesting functional superiority of CKCE.

KEY WORDS closed-kinetic chain, open-kinetic chain, Redcord, 1RM, isokinetic dynamometry, balance

Effect of core stability training on throwing velocity in female handball players.

The purpose was to study the effect of a sling exercise training (SET)–based core stability program on maximal throwing velocity among female handball players. Twenty-four female high-school handball players (16.6 ± 0.3 years, 63 ± 6 kg, and 169 ± 7 cm) participated and were initially divided into a SET training group (n = 14) and a control group (CON, n = 10). Both groups performed their regular handball training for 6 weeks. In addition, twice a week, the SET group performed a progressive core stability-training program consisting of 6 unstable closed kinetic chain exercises. Maximal throwing velocity was measured before and after the training period using photocells. Maximal throwing velocity significantly increased 4.9% from 17.9 ± 0.5 to 18.8 ± 0.4 m_s^{-1} in the SET group after the training period (p < 0.01), but was unchanged in the control group (17.1 ± 0.4 vs. 16.9 ± 0.4 m_s^{-1}). These results suggest that core stability training using unstable, closed kinetic chain movements can significantly improve maximal throwing velocity. A stronger and more stable lumbopelvic-chip complex may contribute to higher rotational velocity in multisegmental movements. Strength coaches can incorporate exercises exposing the joints for destabilization force during training in closed kinetic chain exercises. This may encourage an effective neuromuscular pattern and increase force production and can improve a highly specific performance task such as throwing.

KEY WORDS strength, performance, unstable, closed kinetic

**Abstract.** [Purpose] The aim of the present study was to determine whether a multimodal treatment approach using spinal decompression via SpineMED and spinal mobilization as well as cervical stabilization exercises would benefit patients with neck pain with radiculopathy. [Subjects] A total of 10 patients with cervical radiculopathy ranging in age from 19 to 46 with an average age of 35.50 years participated in this study. [Methods] Patients received treatment in 85 minute sessions, 6 days per week for the first two weeks, and 4 days per week for two additional weeks. Treatment protocol consisted of spinal decompression via SpineMED and flexion-distraction mobilization of the cervical spine as well as cervical stabilization exercises. Physical therapy modalities including superficial heat, ultrasound, and interferential current were also delivered prior to administration of SpineMED. Differences between patients’ pre-intervention and discharge outcome measures, pain on a visual analogue scale (VAS) and neck disability index (NDI), were examined using a paired t-test. [Results] Mean measures of patients’ VAS and NDI demonstrated significant improvement after being treated with 20 sessions of combined treatment. [Conclusion] Findings of the present study provide significant evidence to support the efficacy of a multimodal treatment approach using spinal decompression via SpineMED and spinal mobilization as well as cervical stabilization exercises. A multimodal approach might be an asset in the management of cervical spine disorders.

**Key words:** Cervical radiculopathy, Spinal decompression, Multimodal treatment

Reduced force steadiness in women with neck pain and the effect of short term vibration.

*J Electromyogr Kinesiol* 2010;21(2):283-90

This study compares neck force steadiness in women with neck pain and controls and the way this is influenced by short term vibration of the neck. In the first experiment, 9 women with chronic neck pain and 9 controls performed 10-s isometric cervical flexion at 15 N. Intramuscular EMG was recorded from the sternocleidomastoid muscle. In the second experiment, 10 women with neck pain and 10 controls performed 10-s isometric cervical flexion at 25% of their maximal force before and after vibration to the neck (bursts of 50 Hz with duration 20, 40, 60 and 120 s). Surface EMG was acquired from the sternocleidomastoid and splenius capitis. In both experiments, force steadiness was characterized by the coefficient of variation (CoV) and the relative power in three frequency subbands (low: 0–3 Hz; middle: 4–6 Hz; high: 8–12 Hz) of the force signal. Women with neck pain exhibited decreased force steadiness (Exp 1: patients 3.9 ± 1.3%, controls 2.7 ± 0.9%, P < 0.05; Exp 2: patients 3.4 ± 1.2%, controls 1.7 ± 0.6%, P < 0.01) which was associated with higher power in the low-frequency band (patients 71.2 ± 9.6%, controls 56.7 ± 9.2%, P < 0.01). Following vibration, CoV (2.6 ± 1.1%, P < 0.05) and the power in the low-frequency band of the force signal decreased (63.1 ± 13.9%, P < 0.05) in the patient group. These effects were not present in controls. Motor unit behavior and surface EMG amplitude were similar between groups. In conclusion, women with neck pain have reduced force steadiness, likely due to alterations in Ia afferent input. Vibration, which modulates Ia afferent input, increases force steadiness in patients with neck pain.

Differences in transverse abdominis activation with stable and unstable bridging exercises in individuals with low back pain.

**Background.** The transversus abdominis (TrA) is a spine stabilizer frequently targeted during rehabilitation exercises for individuals with low back pain (LBP). Performance of exercises on unstable surfaces is thought to increase muscle activation, however no research has investigated differences in TrA activation when stable or unstable surfaces are used.

**Objective.** The purpose of this study was to investigate whether TrA activation in individuals with LBP is greater when performing bridging exercises on an unstable surface versus a stable surface.

**Methods.** Fifty one adults (mean ± SD, age 23.1 ± 6.0 years, height 173.60 ± 10.5 cm, mass 74.7 ± 14.5 kg) with stabilization classification of LBP were randomly assigned to either exercise progression utilizing a sling bridge device or a traditional bridging exercise progression, each with 4 levels of increasing difficulty. TrA activation ratio (TrA contracted thickness/TrA resting thickness) was measured during each exercise using ultrasound imaging. The dependent variable was the TrA activation ratio.

**Results.** The first 3 levels of the sling-based and traditional bridging exercise progression were not significantly different. There was a significant increase in the TrA activation ratio in the sling-based exercise group when bridging was performed with abduction of the hip (1.48 ± .38) compared to the traditional bridge with abduction of the hip (1.22 ± .38; p<.05).

**Conclusion.** Both types of exercise result in activation of the TrA, however, the sling based exercise when combined with dynamic movement resulted in a significantly higher activation of the local stabilizers of the spine compared to traditional bridging exercise. This may have implications for rehabilitation of individuals with LBP.

The Efficacy of Spinal Decompression via DRX3000 combined with a Spinal Mobilization and a Lumbar Stabilization Exercise Program for Patients with Discogenic Low Back Pain.

Abstract. [Purpose] The purpose of this study was to determine the effects of motorized spinal decompression using the DRX3000 system (Axiom Worldwide, Tampa, FL, USA) combined with spinal mobilization as well as lumbar stabilization exercises on patients with discogenic low back pain (LBP). [Subjects] A total of 30 adults with discogenic LBP (mean age, 34.06 ± 6.41 years; age range, 28–48 years; 14 males, 16 females) volunteered to participate in this study. [Methods] A 4-week course of spinal decompression treatment combined with motorized flexion-distraction mobilization and lumbar stabilization exercises were administered to the participants for 6 days per week for the first two weeks, and four times per week for two additional weeks. The entire treatment consisted of 20 visits over a 4-week period. Comparisons of changes in the Oswestry Disability Index (ODI) and straight leg raise (SLR) test at pre-intervention, after 10 treatment sessions, and at discharge (after 20 treatment sessions) were analyzed. [Results] There were significant improvements in the outcome measures of ODI score and SLR test after 10 and 20 sessions of spinal decompression treatment combined with spinal mobilization and lumbar stabilization exercises as compared with the pre-intervention. [Conclusion] Spinal decompression treatment combined with spinal mobilization and lumbar stabilization exercises significantly improved the clinical outcome measures of ODI score and SLR test in patients with LBP secondary to intervertebral disc herniation.

Background. Exercise benefits patients with chronic nonspecific low back pain; however, the most effective type of exercise remains unknown.

Objective. This study compared outcomes after motor control exercises, sling exercises, and general exercises for low back pain.

Design. This was a randomized controlled trial with 1-year follow-up. Setting. The study was conducted in a primary care setting in Norway.

Patients. The participants were patients with chronic nonspecific low back pain (n = 109).

Interventions. The interventions in this study were low-load motor control exercises, high-load sling exercises, or general exercises, all delivered by experienced physical therapists, once a week for 8 weeks.

Measurements. The primary outcome measure was pain reported on the Numeric Pain Rating Scale after treatment and at a 1-year follow-up. Secondary outcome measures were self-reported activity limitation (assessed with the Oswestry Disability Index), clinically examined function (assessed with the Fingertip-to-Floor Test), and fear-avoidance beliefs after intervention.

Results. The postintervention assessment showed no significant differences among groups with respect to pain (overall group difference) or any of the outcome measures. Mean (95% confidence interval) group differences for pain reduction after treatment and after 1 year were 0.3 (0.7 to 1.3) and 0.4 (0.7 to 1.4) for motor control exercises versus sling exercises, 0.7 (0.6 to 2.0) and 0.3 (0.8 to 1.4) for sling exercises versus general exercises, and 1.0 (0.1 to 2.0) and 0.7 (0.3 to 1.7) for motor control exercises versus general exercises.

Limitations. The nature of the interventions made blinding impossible.

Conclusions. This study gave no evidence that 8 treatments with individually instructed motor control exercises or sling exercises were superior to general exercises for chronic low back pain.

Abdominal muscle contraction thickness and function after specific and general exercises: A randomized controlled trial in chronic low back pain patients.

The aim of this study was to assess changes in deep abdominal muscle function after 8 weeks of exercise in chronic low back pain patients. Patients (n = 109) were randomized to specific ultrasound guided, sling or general exercises. Contraction thickness ratio in transversus abdominis (TrA), obliquus internus (OI) and externus (OE), and TrA lateral slide were assessed during the abdominal drawing-in maneuver by b-mode ultrasound. Changes in abdominal muscle function were also regressed on changes in pain. Only modest effects in deep abdominal muscle function were observed, mainly due to reduced activation of OI (contraction thickness ratio: 1.42e1.22, p = 0.01) and reduced TrA lateral slide (1.26e1.01 cm, p = 0.02) in the ultrasound group on the left side. Reduced pain was associated with increased TrA and reduced OI contraction ratio (R² = 0.18). It is concluded that 6e8 treatments with specific or general exercises for chronic low back patients attained only marginal changes in contraction thickness and slide in deep abdominal muscles, and could only to a limited extent account for reductions in pain.

Neurac – a new treatment method for chronic musculoskeletal pain.
Tidsskriftet Fysioterapeuten 2009:76(12)16-25

The effect of exercise therapy on chronic musculoskeletal pain is generally low and moderate at best. In this paper a new exercise treatment method, Neurac, is described with theoretical background, development, main content, and documentation.

Neurac is a treatment method that aims at regaining normal functional movement patterns in patients with musculoskeletal disorders, by using high levels of neuromuscular stimulation.

This is an active treatment approach including four main elements: 1. Bodyweightbearing exercises utilizing the Redcord sling system, 2. Controlled vibration to selected body parts, 3. Gradual increase of resistance (work-load), 4. No pain or no increase of existing pain.

A newly developed vibration apparatus, Redcord Stimula, is often used to augment neural adaptions by a potential increase in activation of muscle spindles. The Neurac method also includes testing procedures for neuromuscular function of the kinetic chains, and the integration of «local» and «global» muscle function.

Theoretically, Neurac is based on supporting research on bodyweightbearing exercises loading the biomechanical chains. Further, based on neuroscience and clinical trials the method utilizes vibration to increase neural drive and to decrease pain.

The development of the Neurac-methodology has emerged from the S-E-T concept (Sling Exercise Therapy). The new methodology involves use of the Redcord Trainer (formerly called TerapiMaster), workstation and the vibration apparatus.

Documentation: Systematic observations in the clinic show changes after implementation, but research is needed to evaluate the efficiency of the Neurac-method as a physiotherapeutic tool.

Abstract

An analysis of data obtained in an experiment investigating the influence of stability training of the lumbo-pelvo-hip complex (LPHC) on stiffness of the hamstrings is presented. Randomized controlled trial. The study included 30 subjects (aged 18–42 years) with increased stiffness of the hamstrings at baseline. Over a period of 4 weeks, stability training aiming to activate the deep stabilizing muscle subsystem and to integrate its action with the superficial subsystem was introduced in the experimental group. The control group remained unaffected. Three series of measurements were applied (baseline, after 2 weeks, and after 4 weeks). A digital inclinometer was used to measure outcomes of passive knee extension in the supine test. In the experimental group, a tendency to decrease stiffness of the hamstrings was observed. It was the opposite in the control group. Significant intra-group differences in the experimental group between series 1 and 3 measurements for both the right and left lower extremities were revealed. Stability training of the LPHC showed a tendency to be effective in reducing stiffness of the hamstrings.

Closed-kinetic chain upper-body training improves throwing performance of NCAA Division I Softball players.

Journal of Strength and Conditioning 2008;22(6):1790-8

Closed–kinetic chain resistance training (CKCRT) of the lower body is superior to open–kinetic chain resistance training (OKCRT) to improve performance parameters (e.g., vertical jump), but the effects of upper-body CKCRT on throwing performance remain unknown. This study compared shoulder strength, power, and throwing velocity changes in athletes training the upper body exclusively with either CKCRT (using a system of ropes and slings) or OKCRT. Fourteen female National Collegiate Athletic Association Division I softball player volunteers were blocked and randomly placed into two groups: CKCRT and OKCRT. Blocking ensured the same number of veteran players and rookies in each training group. Training occurred three times weekly for 12 weeks during the team’s supervised off-season program. Olympic, lower-body, core training, and upper-body intensity and volume in OKCRT and CKCRT were equalized between groups. Criterion variables pre- and posttraining included throwing velocity, bench press one-repetition maximum (1RM), dynamic single-leg balance, and isokinetic peak torque and power (PWR) (at 180°/s) for shoulder flexion, extension, internal rotation, and external rotation (ER). The CKCRT group significantly improved throwing velocity by 2.0 mph (3.4%, p < 0.05), and the OKCRT group improved 0.3 mph (0.5%, NS). A significant interaction was observed (p < 0.05). The CKCRT group improved its 1RM bench press to the same degree (1.9 kg) as the OKCRT group (p < 0.05 within each group). The CKCRT group improved all measures of shoulder strength and power, whereas OKCRT conferred little change in shoulder torque and power scores. Although throwing is an open-chain movement, adaptations from CKCRT may confer benefits to subsequent performance. Strength coaches can incorporate upper-body CKCRT without sacrificing gains in maximal strength or performance criteria associated with an athletic open-chain movement such as throwing.

KEY WORDS resistance training, open–kinetic chain, shoulder peak torque, shoulder power
Re-activation of deep local stabilizing muscles of the spine has been demonstrated to be an essential part of rehabilitation for the musculoskeletal system and, in particular, mechanical spine pain.

How many people would think of using some form of exercise as primary pain management? If you’re the typical practitioner who perhaps doesn’t get the opportunity to read the latest research in the sport sciences, you might answer, “Not many.” In this clinical report, I would like to draw attention to the increasing body of research appearing in both the strength/conditioning and pain therapy realms that is providing evidence for lumbo-pelvic core stabilization training as a method to restore normal function while, at the same time, reducing spinal pain. There is still continuing debate as to which specific methods are the best, but a general consensus is forming regarding the presence of a muscle impairment component to many of the mechanical/idiopathic low back pain syndromes being seen by practitioners today.1 The phrase ‘core stabilization training’ has become popular and somewhat in vogue with trainers and therapists alike. Stabilization is not the same as strengthening yet many practitioners continue to use the terms synonymously. The Redcord method of core stabilization was developed in Norway in the 1990s and represents one of the most popular techniques for specific core stabilization treatment through neuromuscular re-activation (neurac). We will begin our discussion with semantic clarifications while examining the main premise behind Redcord therapy.

The effects of sensorimotor training on knee proprioception and function for patients with knee osteoarthritis: a preliminary-report.
Clin Rehabil 2008;22;448-57

**Objective:** To investigate the effects of a sensorimotor training programme in osteoarthritic patients.

**Design:** Randomized, single-blind, controlled trial.

**Setting:** Kinesiology laboratory at School of Physical Therapy.

**Participants:** A total of 60 patients were randomly assigned to the training group and the control group. Only 29 patients (training group, 15; control group, 14) completed the study.

**Intervention:** The training group underwent a sensorimotor training programme using a sling suspension system complemented by a routine physical therapy. The control group underwent a routine physical therapy.

**Main measures:** Active joint repositioning, functional testings, and self-reported function with the Western Ontario & McMaster Universities Arthritis Index before and after the eight-week intervention.

**Results:** There were significant differences between the two groups with respect to the improvement in proprioception as measured by active joint repositioning (the changes in the absolute error were 1.91.7, training group versus 0.12.8, control group (P<0.05), and in self-reported functional difficulty (33.235.1, training group versus 8.010.2, control group; P<0.05)). There was no significant difference between the two groups in other outcomes.

**Conclusion:** A sensorimotor training using a sling suspension system improved the patients’ proprioception in the knee joints and their self-reported function. Thus, these exercises may serve as an exercise programme for patients with knee osteoarthritis.

English title: Treatment of low back pain and effectiveness of Sling-Exercise-Therapy (S-E-T).

An experimental study was carried out to compare S-E-T-Training versus conventional strength-training regarding their effectiveness in the therapy of low back pain. The parameters of interest were maximum strength of the trunk muscles (flexion/extension), spine stabilization, pain intensity and general well-being. The S-E-T Training method proved to be highly effective in improving trunk-stabilization. There were no significant differences concerning the maximum strength. Both training groups were able to reduce their pain intensity and increase their general well-being.

**Key words:** Chronic low back pain, therapy, Sling-exercise-Therapy

A randomized study of new sling exercise treatment vs traditional physiotherapy for patients with chronic whiplash-associated disorders with unsettled compensation claims.

BACKGROUND: Many patients with chronic whiplash-associated disorders have reduced neuromuscular control of the neck and head. It has been proposed that a new sling exercise therapy may promote neuromuscular control of the neck.

OBJECTIVES: To compare the effects of traditional physiotherapy vs traditional physiotherapy combined with a new sling exercise therapy on discomfort and function in patients with chronic whiplash-associated disorders who have unsettled compensation claims; and to investigate possible additional effects of guided, long-term home training.

DESIGN: A randomized multi-centre trial with 4 parallel groups.

METHODS: A total of 214 patients were assigned randomly to 4 treatment groups, and received either traditional physiotherapy with or without home training, or new sling exercise therapy with or without home training. Outcome measures were pain, disability, psychological distress, sick leave and physical tests.

RESULTS: A total of 171 patients (80%) completed the study. There were no important statistical or clinical differences between the groups after 4 months of treatment. There was a small statistically significant effect at 12-month follow-up in both groups with home training regarding pain during rest ($p = 0.05$) and reported fatigue in the final week ($p = 0.02$).

CONCLUSION: No statistically significant differences were found between the traditional physiotherapy group and the new sling exercise group, with or without home training. Since the groups were not compared with a control group without treatment, we cannot conclude that the studied treatments are effective for patients with whiplash-associated disorder, only that they did not differ in our study.

Sling Exercise Training improves balance, kicking velocity and torso stabilization strength in elite soccer players.

*Medicine & Science in Sports & Exercise* 2006;38(5):243

**Purpose:** To determine the impact of a Sling Exercise Training (SET) core stability program on postural balance, kicking velocity, functional strength, and back pain in elite level soccer players.

**Method:** 12 Norwegian 1st division soccer players completed 8 wk x 2 d wk⁻¹ SET training with a main focus on the hip and trunk area. Each training session, athletes performed 8 different highly unstable, closed kinetic chain exercises in adjustable slings. Exercise difficulty was progressed by increasing the resistance arm and degree of instability. 4 of the training group had suffered extended periods of low back pain. 9 players of similar performance level served as a control group.

**Results:** **Balance:** Mean one-legged eyes closed COP sway velocity moment decreased 45% in the worst leg (p < 0.01) and 18% in the best leg (p = 0.113). The mean difference in velocity moment between the legs was reduced from 51% to 3% (p = 0.001). No change in balance performance was observed in the control group. **Kicking:** Ball velocity during one-step maximal velocity kicking (preferred leg) increased significantly in the training group (3.5%,) compared to controls (-2.3%, p = 0.04). **Torso functional strength:** The 4 subjects with chronic low back all reported that pain was reduced after training. The training group, and particularly chronic low back pain subjects, significantly improved in a clinical test of pelvic rotational stability (p < 0.01, see picture of test condition).

**Conclusion:** This unique functional stability training program involving movements performed in unstable slings clearly improved static balance and reduced low back pain. In addition, a small but significant improvement in kicking performance was observed. To our knowledge this is the first study to demonstrate a direct performance enhancing effect of a core stability training program. Functional strength training in slings appears to be an effective modality for enhancing neuromuscular control and joint stability.
Seiler S, Skaanes PT, Kirkesola G.
Effects of Sling Exercise Training on maximal clubhead velocity in junior golfers.
*Medicine & Science in Sports & Exercise* 2006;38(5):286

**Purpose:** To determine the impact of a Sling Exercise Training (SET) core stability program on maximal club-head velocity in competitive junior golf players.

**Methods:** 2 teams of junior golfers (SET 15±2 yr 13 handicap, CON 15.8 yr 6 handicap) performed either 9 wks x 2 wk⁻¹ specific core and rotational stability training (SET, n=10), or standard strength training 2 wk⁻¹ (CON, n=10). Maximal club-head velocity was measured over 10 trials before and after the intervention period using a dedicated velocity measurement system.

**Results:** Preliminary within-days learning effects trials showed very stable stroke to stroke velocity (CV 1.6%). Between days (~7 days) reliability for maximal club-head velocity was also excellent (r=0.99, mean diff= 0.1 m sec⁻¹). Baseline performance was similar in both groups (SET 42.1±4.1 m s⁻¹, CON 42.7±5.7 m s⁻¹). However, at post-test SET increased club head velocity 3.8% (95% CI 2.6-4.8%, p< 0.001) compared to 1.2% in CON (95% CI 0.0-1.0%, p=0.05). Standing balance in the golf swing position was also measured using a computerized balance platform. However, no significant balance changes were observed in either group.

**Conclusions:** A unique functional stability program consisting of progressively unstable, closed kinetic chain exercises for the hips and torso appears to improve rotational power in a highly specific performance task. The magnitude of the improvement (Effect Size= 0.4) is small but meaningful from a performance standpoint (equivalent to 10-15m increase in drive distance). This is to our knowledge one of the first studies to demonstrate a transfer of generalized core stability training to a specific performance task.
Brage S, Lærum E, Herland K.

The effect and experiences by implementing the sling training concept "S-E-T Corporate" in Norwegian IA companies.

The purpose of the study to evaluate implementing S-E-T Corporate in a number of Norwegian companies and to compare this intervention to other traditional physiotherapeutic interventions. The study lasted for 12 months and was initiated in March 2003. Participants in the intervention group (80 employees in 6 companies) training S-E-T obtained a significant improvement in functional ability and self reported physical health. In the control group (37 employees in 4 companies) there were no improvements in the functional ability and self reported health. There was no significant decrease in sick leave in either of the two groups but in some companies which had a high sick leave prior to project there were reductions in sick leave after implementing S-E-T. What seemed to be the "common factor" in the companies that did get a reduction in sick leave was encouraged company leadership and encouraged physiotherapist with a good S-E-T knowledge.
Stuge B, Lærum E, Kirkesola G, Vøllestad N:
The Efficacy of a Treatment Program Focusing on Specific Stabilizing Exercises for Pelvic Girdle Pain After Pregnancy. A Randomized Controlled Trial.

Study Design. A randomized controlled trial with stratified block design.

Objectives. To evaluate a treatment program focusing on whether specific stabilizing exercises for patients with pelvic girdle pain after pregnancy reduce pain, improve functional status, and improve quality of life.

Summary of Background Data. The evidence of effectiveness of treatment for pelvic girdle pain is weak. Recent research has focused on the importance of activation of muscles for motor control and stability of the lumbopelvic region. To the authors’ knowledge, the efficacy of applying these principles for pelvic girdle pain has not previously been evaluated in a randomized controlled trial.

Methods. Eighty-one women with pelvic girdle pain were assigned randomly to two treatment groups for 20 weeks. One group received physical therapy with a focus on specific stabilizing exercises. The other group received individualized physical therapy without specific stabilizing exercises. Assessments were administered by a blinded assessor, at baseline, after intervention and 1 year post partum. Main outcome measures were pain, functional status and quality of life.

Results. There were no dropouts. After intervention and at 1 year post partum, the specific stabilizing exercise group showed statistically and clinically significant lower pain intensity, lower disability, and higher quality of life compared with the control group. Group difference in median values for evening pain after treatment was 30 mm on the Visual Analog Scale. Disability was reduced by more than 50% for the exercise group; changes were negligible in the control group. Significant differences were also observed for physical tests, in favor of the specific exercise group.

Conclusion. An individualized treatment approach with specific stabilizing exercises appears to be more effective than physical therapy without specific stabilizing exercises for women with pelvic girdle pain after pregnancy.

Key words: pelvic girdle pain, postpartum, randomized controlled trial, physical therapy, specific stabilizing exercises, effectiveness
Stuge B, Veierød M B, Lærum E, Vøllestad N.

The Efficacy of a Treatment Program Focusing on Specific Stabilizing Exercises for Pelvic Girdle Pain After Pregnancy. A Two-Year Follow-up of a Randomized Clinical Trial.

*SPINE* 2004;29(10):E197-203

**Study Design.** A randomized clinical trial.

**Objectives.** To examine the effects of a treatment program focusing on specific stabilizing exercises after a 2-year follow-up period.

**Summary of Background Data.** An individualized treatment approach with specific stabilizing exercises is shown to be effective for women with pelvic girdle pain 1 year after delivery. No previous study has examined the long-term effects of treatment for women with postpartum pelvic girdle pain.

**Methods.** Eighty-one women with pelvic girdle pain postpartum were assigned randomly to 2 treatment groups for 20 weeks. Patient self-reported questionnaires measuring pain, disability, and health-related quality of life were collected after 20 weeks of treatment and 1 and 2 years postpartum.

**Results.** All 81 women returned the questionnaires for the 2-year follow-up. Sixteen were excluded from the analysis, mainly due to new pregnancies. The significant differences between the groups in functional status, pain, and physical health (SF-36) were maintained 2 years after delivery. Minimal disability was found in 85% of the specific stabilizing exercise group as compared to 47% in the control group. The control group showed significant improvement in functional status with median change score of 6.0 (Q1–Q3 of 12–0). Minimal evening pain was reported by 68% in the specific stabilizing exercise group versus 23% in the control group. However, the group differences disappeared for all measures when controlling for score level 1 year after delivery by regression analysis.

**Conclusion.** The significant differences between the groups persisted with continued low levels of pain and disability in the specific stabilizing exercise group 2 years after delivery. Significant reduction in disability was found within the control group. Those with the highest level of disability and greatest potential for improvements recovered most, regardless of intervention group.

Key words: pelvic girdle pain, postpartum, randomized controlled trial, physical therapy, specific stabilizing exercises, effectiveness, follow-up
Nordisk Terapi AS, SINTEF Health Research, selected key professionals and three municipalities, Arendal, Bærum and Lunner, have carried out the pilot project “Active rehabilitation and training of elderly people”. The Norwegian Industrial and Regional Development fund (SND) has supported the project. During the pilot project we have:

- Investigated the needs for active rehabilitation and training of elderly people in connection with fractures, brain strokes and other chronic conditions
- Established co-operation between the health care sector, industry and research institutes as well as contact with the National Insurance Administration (RTV)
- Carried out seven basic training courses for professionals on the use of TerapiMaster
- Worked out a project proposal for the development of new concepts for active rehabilitation for elderly people based on S-E-T (Sling Exercise Therapy)

Traditionally there has been a lack of resources in the rehabilitation field, but now the need for development in the rehabilitation field seems to be recognised. Professionals emphasise that rehabilitation must be a priority because rehabilitation represents an investment in future possibilities and results. The parliamentary document on rehabilitation and subsequent follow-up shows that the Norwegian authorities are working towards increased focus on rehabilitation and in particular the users’ own active participation in the process.

Co-operation across services is vital, giving the elderly a holistic rehabilitation process, starting off with surgery, moving on to treatment in the nursing home, training in the physiotherapy clinic and finally transfer to the users home. Such a complete concept, combined with thorough user training is important in order to feel safe and motivated for making the effort to exercise. The complete concept depends on close co-operation between all involved parties, mainly nursing staff and physiotherapists. In Lunner municipality, the pilot project has showed how using TerapiMaster can be a link between different health care services thus exchanging professional points of view and improving collaboration in the rehabilitation process.

The pilot project, in particular the investigation into needs, and the parliamentary document, points out the need for further training and follow-up of health service personnel. Furthermore there is a need for a long-term strategy on development of expertise and research in the rehabilitation field. It is also evident that there is a need for better documentation regarding the benefits and effect of alternative rehabilitation methods. The results of active training must be documented and made public to the users themselves, to professionals, local health care services and the authorities. Practical examples of cost/effect analysis indicate that a reasonable investment such as S-E-T with TerapiMaster combined with training and active follow-up can increase functional ability and quality of life thus representing a saving for society by means of reduced costs in connection with various forms of care. Health care personnel have responded with many positive experiences using the S-E-T concept and TerapiMaster in connection with treatment and training together with patients and also as a means to relieve the therapist.

The summary states: “Practical examples of cost-benefit analyses indicate that a reasonable investment such as S-E-T using the TerapiMaster combined with instruction and active follow-up, can increase the level of functioning and quality of life and save society considerable outlays for institutionalization and care.”

An article about this project appeared in Geriatrix.

This report is available only in Norwegian.
Sling Exercise Therapy (S-E-T) is a total concept for active treatment and exercise with the aim of contributing to permanent improvement of musculoskeletal disorders. The model is based on what are assumed to be the key elements of active training and rehabilitation today (which are described and documented in this article). The concept, which has been developed in Norway over the past eight years, is also used in the treatment of strokes and other neurological conditions, for stimulating children and for fitness training. This article focuses on treatment of musculoskeletal disorders. The S-E-T concept consists of a system of diagnosis and treatment. The system of diagnosis involves testing of the muscles’ tolerance through progressive loading in open and closed kinetic chains, and is used together with conventional examinations in diagnosing musculoskeletal disorders. The treatment system contains elements such as relaxation, increasing the range of movement, traction, training the stabilizing musculature, sensorimotor exercises, training in open and closed kinetic chains, dynamic training of the mobilizing musculature, fitness training, group exercise, personal exercise at home with long-term follow-up, and computer software for setting up and modifying exercises. The concept has been developed in the light of current knowledge regarding active treatment and exercise for musculoskeletal disorders. Although clinical experience with the S-E-T concept has been positive, there is a lack of scientific evidence. Therefore research has been heavily emphasized. A randomized study of the effect of personal exercise at home on chronic back pain and a pilot study of the effect of active treatment and personal exercise at two companies in Norway have been published. A randomized study on the treatment of Whiplash Associated Disorders was implemented in 1999. During the current year studies on the effect of training of the elderly, on the effect of active treatment and exercise at the workplace combined with home exercise, exercises in the treatment of unstable shoulders and training of athletes will be initiated.

This article was also published in Krankengymnastik, Germany in March 2001.
Moe K, Thom E.
The effect of regular exercise on absenteeism due to illness. Results of an intervention study.
*Tidsskriftet Fysioterapeuten* (Special Issue), December 2001

The background for this prospective not-randomized study was to evaluate if regular training can reduce sick leave for employees having musculoskeletal problems. 33 employees (14 women / 19 men) in two Norwegian industrial companies, having shoulder, neck and back problems, participated in 12 month period. The Norwegian developed S-E-T concept was used as training intervention.

The S-E-T (Sling Exercise Therapy) program consisted of regular relaxation exercises performed at the workplace, and individual training at home three times per week. The training program was developed by an experienced physiotherapist. Results from the study showed that relaxation and physical training, in combination with follow-up and assistance by a physiotherapist, can significantly reduce the sick leave for employees have musculoskeletal problems.

33 employees of two Norwegian industrial enterprises with neck, shoulder and back problems reduced their specific absenteeism by a total of 558 days, i.e. 14.7 days per man-year, which amounted to 80% of the absenteeism due to musculoskeletal ailments. Total absenteeism was reduced by 437 days, i.e. 11.5 days per man-year. This reduction was sustained the year after the intervention.

The article is only available in Norwegian.
Moe K, Thom E.
Musculoskeletal disorders and physical activity. Results of a long-term study.
Tidsskriftet for Den norske Lægeforening 1997;29:4258-61

In two Norwegian industrial companies, 42 employees (24 female / 18 male) with shoulder, neck and back problems, took part in a training program over a 12-month period. The program comprised daily relaxation exercises at work combined with training at home for about 30 minutes three times a week. The Norwegian-designed physiotherapy and training apparatus, TerapiMaster, was used both at work and at home. The training program was developed and monitored by an experienced physiotherapist.

The observations made during the training program focused on changes in the rate of absence due to illness during the study compared with the pre-study rate of absence due to illness.

For employees with musculo-skeletal ailments, the combination of relaxation exercises and physical training, with professional instruction and follow-up, significantly reduced the rate of absence due to illness from 11.2 days per year (Pre-study) to 0.2 days per year (at the end of the 12-month training period) (p<0.001)

A follow-up 30 months after completion of the formal study showed that absence due to illness had remained at the reduced rate, probably because positive experiences and 'good habits' formed during the study encouraged the participants to continue the training program.

The article is only available in Norwegian.

Effect on sick leave due to low back pain. A randomized, comparative, long-term study.

*SPINE* 1997;22:1610-6

**Study Design.** The study was carried out as an open randomized, multicenter, parallel-group study with an observation period of 12 months. Four Norwegian physiotherapy institutes took part. Patients were subsequently followed for 12 months of home exercise on their own, without the supervision of a physiotherapist.

**Objectives.** 1) To investigate and compare the effects of two different exercise programs on low back problems in patients after a 1-year training program under the supervision of a physiotherapist. 2) To investigate the effect supervision by, and motivation from, physiotherapists has on training compliance and efficacy.

**Summary of Background Data.** After ordinary physiotherapy treatment for low back problems, patients were randomly allocated either to a conventional training program designed by physiotherapists or to a training program using a new Norwegian-developed training apparatus called the TerapiMaster. The study included 153 patients with low back problems, all of whom had been referred to physiotherapy by their general practitioners. One hundred twenty-six patients were followed for an additional 12 months when performing home exercise programs on their own.

**Methods.** Monitoring patient satisfaction with the training program, compliance with the program, and absenteeism from work during the training period.

**Results.** Patient satisfaction with both training programs was high, with about 83% of participating patients completing the study in accordance with the protocol. Mean absenteeism (SD) during the preceding year totaled 82.5 days (19.8) in the conventional training group and 61.6 days (14.7) in the TerapiMaster group. Significant reductions to 17.2 days (6.0) and 15.4 days (5.3) in the two groups, respectively, were recorded during the training period, corresponding to a 75% to 80% reduction compared with the preceding 1-year period. Mean absenteeism showed a further significant decline during the 12-month period without supervised training. The average values were 9.9 days (3.2) for conventional training and 9.3 days (3.1) for the TerapiMaster, respectively.

**Conclusion.** Both exercise programs reduced absenteeism significantly (75-80%). No difference in the effects of the two different programs was discernible. Regular follow-up through encouragement and variation in the training programs appear to be important factors for motivating patients to adhere to regular exercise programs for low back problems. This thesis was corroborated by the 12-month study of unsupervised exercise.
